Exploring mobility dynamics in FVG - part 1: data preparation

Context and objectives

The dataset consists of information regarding mobility within the Region and includes the followinf information: origin and destination, number of journeys, date, time and type of journey. Specifically, each entry in the dataset represents a group of journeys undertaken by individuals.

The dataset also includes date and time feature: journeys are grouped by day and into blocks of three hours. Additionally, the 'type' attribute distinguishes between residents and tourists, and for residents between inbound and outbound journeys.

The purpose of this notebook is data preparation and exploration of the dataset 'mobilityFVG'.

The main output is a tidy dataset in .csv format.

Data preparation

The dataset is provided as multiple Excel files (.xlsx format), and requires cleaning for analysis. Tasks include:

- Consolidating multiple xlsx files into a single .csv file to ensure data consistency and facilitates streamlined analysis
- Renaming variables to English
- Removing special characters and whitespaces
- Derive categorical variables from the 'type' column, simplifying them into more efficient categories such as 'inbound' and 'outbound'
- Set appropriate date format, and calculate weekday (1 = Monday)

• Eliminating unnecessary columns.

The R code utilizes the 'readxl' package to import data from Excel files and the 'tidyverse' package for efficient data manipulation. Specifically, tidyverse' an efficient syntax and verbs like 'mutate', 'rename', and 'select' to clean and preprocess the dataset, enhanching readability and facilitating code debug and reuse.

```
library(tidyverse)
library(readxl)
library(gridExtra)
```

Data sources for this notebook

Parameters for data preparation: columns to keep and their new names

Define a function that reads a single file and processes data:

```
# remove unnecessary columns
    select(all_of(selected_cols)) %>%
    # rename columns
    setNames(new_column_names) %>%
    #replace spaces with _ in column names
    rename_with(~ gsub(" ", "_", .), everything()) %>%
    #remove special characters such as ò, à ...
    mutate(across(where(is.character), ~ gsub("[^a-zA-Z0-9\\s]", " ", .))) %>%
    #set appropriate format for Day and get weekday
    mutate(day = as.Date(day, format = "%d-%m-%Y")) %>%
    mutate(weekday = as.numeric(format(day, "%u"))) %>%
    # encode direction as inbound or outbound
    mutate(direction = case_when(
      grepl("di ritorno da altro Comune", type) ~ "inbound",
      grepl("diretto in altro Comune", type) ~ "outbound",
      TRUE ~ "--")) %>%
    # encode type of traveller
    mutate(res_trav = case_when(
      grepl("Residente", type) ~ "resident",
      grepl("Viaggiatore", type) ~ "traveller",
      TRUE ~ "--")) %>%
        select(-type)
       return(df)
  }
apply the function to each file and save in a single dataframe
  data <- data.frame()</pre>
  for (filename in input_files){
      print(paste("Reading and processing", filename))
      df <- read_excel(filename)</pre>
      if( all(column_names == colnames(df)) ){
          print("Colnames are OK, adding data.")
          data <- rbind(data,</pre>
                         read_and_clean(df,
```

```
selected cols,
                                      new_column_names))
      } else {
          print("Column names do not match: skipping this file!")
  }

Data Exploration

time frame

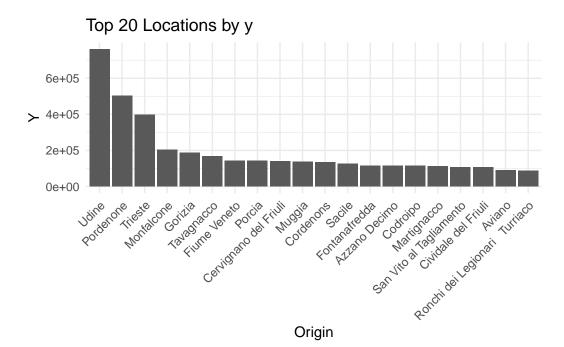

```
data %>% ggplot(aes(x = day)) +
  geom_histogram(binwidth = 1, fill = "skyblue", color = "black") +
  labs(title = "Distribution of Day", x = "Day", y = "Frequency")
```

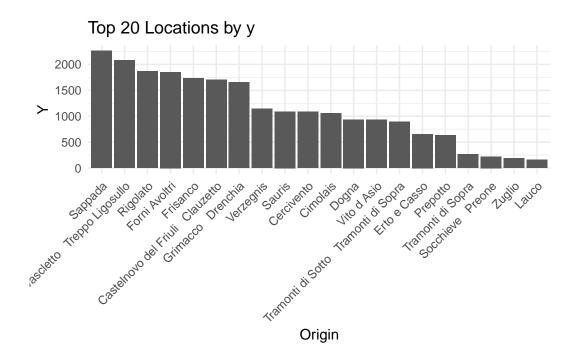

locations

```
theme(axis.text.x = element_text(angle = 45, hjust = 1))
```

last 20

```
locations %>%
   tail(20)%>%
   ggplot(aes(x = reorder(origin, -y), y = y)) +
geom_col() +
labs(title = "Top 20 Locations by y",
        x = "Origin",
        y = "Y") +
theme_minimal() +
theme(axis.text.x = element_text(angle = 45, hjust = 1))
```

Improve information on locations

This section aims to enrich the data on the *origin* and *destination* with latitude, longitude, area, and province according to the ISTAT data on *comuni*.

We must take into account that some locations in the dataset are composed of two *comuni*, hence we need to summarize the information:

- mean Latitude and, longitude
- sum of area
- Name and province of the first enrty in the list.

```
comuni<-read_excel('./data/comuniFVG.xlsx') %>%
    arrange(location, nome)

#check duplicates
duplicate_locations <- comuni %>%
    group_by(location) %>%
```

```
arrange(location)%>%
    filter(n() > 1)
  print(duplicate_locations)
